

Defect 1 – Notification panel renders behind other content | Severity: Medium When the notification panel is opened, it appears behind other UI elements instead of on top. This is a UI layering issue caused by an incorrect z-index or a parent element with overflow hidden creating a clipping context. To fix this, apply a high z-index (e.g. 9999) to the notification panel and ensure it uses position fixed or absolute outside of any clipping parent. This should be tested across all pages as different layouts may introduce new stacking contexts.

Defect 2 – Verification status inconsistent between task page and assigned task | Severity: High The verification state shown on the task page does not always match what is displayed on the assigned task view, making it unclear which state is accurate. This is likely caused by the two views maintaining separate local states instead of sharing a single source of truth. The fix involves ensuring both views read from the same API endpoint or shared state store, and that any verification change triggers a refresh across all relevant views.

Defect 3 – End date can be set before start date | Severity: Critical The system currently allows a due date to be set earlier than the start date, which corrupts task timeline data and breaks any scheduling or duration logic. Both client-side and server-side validation must be added. On the date picker, the minimum selectable due date should be dynamically set to the current start date. On the backend, submissions where due date is earlier than start date should be rejected with a clear error message.

Defect 4 – Task can be created without a start or due date | Severity: Critical Tasks can be saved without any dates, which undermines scheduling, deadline tracking, and filtering features. Both date fields should be marked as required, with clear indicators in the form and validation that prevents submission if either field is empty. If undated tasks are a valid use case, it should be an explicit opt-in toggle rather than an accidental omission.

Defect 5 – Members cannot leave a workspace after joining | Severity: High Once a member joins a workspace, there is no option to leave it. This is both a usability gap and a privacy concern, particularly if someone joined by mistake. A "Leave workspace" option should be added in workspace settings, with a confirmation step. Edge cases such as the leaving member being the sole admin should prompt an ownership transfer before departure is allowed.

Defect 6 – No option to unverify a verified task | Severity: High Once a task is marked as verified, the action cannot be undone. This means any accidental or incorrect verification permanently locks the task with no recovery path. An "Unverify" button or toggle should be added for users with the appropriate permissions, ideally accompanied by a confirmation dialog. A verification history log showing who changed the status and when would also be beneficial for accountability.
